CHAPTER 1

Welcome

Approximate Time: 35 minutes

Welcome to the Styles Tutorial—Understanding the Basics.

- **Tutorial Goal** Learning how to approach styles by using a stylesheet for designing and editing a project, and becoming comfortable with style components in Flare Desktop.
- **Key Concepts** Working with styles in Flare Desktop, getting to know the Stylesheet Editor, and using stylesheets vs. local formatting.

Styles are used to control the look and feel of your documentation, and keep the content separate from its presentation. The styling is based on cascading stylesheets (CSS), which is an international standard for formatting web content, developed by the World Wide Web Consortium (or [W3C](http://www.w3.org/)).

CHAPTER 2

Creating a Project From a Template

To start, let's create a new project based on Flare's Austin template.

I How to Create a New Project From a Template

1. Select **File > New Project**. The Start New Project Wizard opens.
2. In the **Project name** field, give your project any name you want.
3. (Optional) In the **Project folder** field, you can enter a location where you want to save your project. By default, projects are saved in your Documents > My Projects folder.
4. Click **Next**.
5. Under **Factory Templates**, expand the **Tutorials** folder. Select the **Austin** template.

6. Click **Next**.
7. For branding, keep the default settings. (This is where you could customize your project's look with branding, such as colors and logo.) Click **Next**.
8. Click **Finish**. The project is created and loaded into Flare Desktop.

CHAPTER 3

Accessing Stylesheets

In this tutorial, we are going to work with the stylesheet that comes with the Austin template project. The name of the file is Styles.css.

I How to Locate Stylesheets in Flare Desktop

With a new project open, you can find stylesheets a couple of ways.

1. From the Content Explorer, expand **Resources > Stylesheets**. This is the default location for regular stylesheets, and you'll notice the Styles.css file.

 **NOTE** It is recommended to keep the stylesheets in the **Resources > Stylesheets** location, but you can store them anywhere in the Content Explorer.

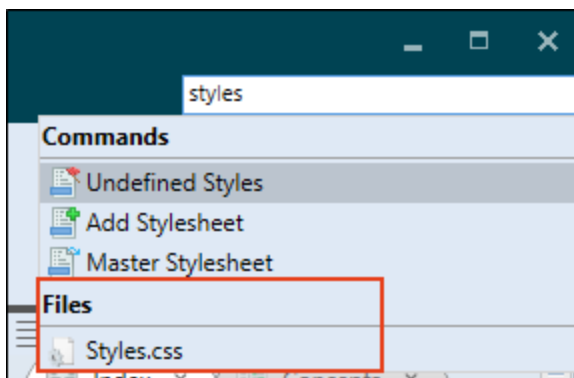

2. Double-click the **Styles.css** file. The stylesheet opens in a Stylesheet Editor, where you can make edits.
3. Close the Stylesheet Editor (in effect, closing the Styles.css file).

4. From Flare Desktop's Quick Launch at the top-right of the application, type `styles`.

5. From the context menu that auto-populates with your search, under the **Files** section, select the **Styles.css** file. This is an alternative way to quickly locate and open a stylesheet.

NOTE Stylesheets exist separately from other content files. This means that topics are referencing an external stylesheet for styles. Because of this, you can maintain and reuse multiple style properties and behaviors from a single location.

CHAPTER 4

Stylesheet Editor Interface

Let's take a closer look at the Stylesheet Editor and the two basic user interface views. The editor offers a Simplified view or an Advanced view for creating or editing styles within the regular stylesheet. Which one you decide to use in your workflow really depends on preference and what you want to do with styles. (You can also toggle between the views at any time.)

This chapter discusses the following:

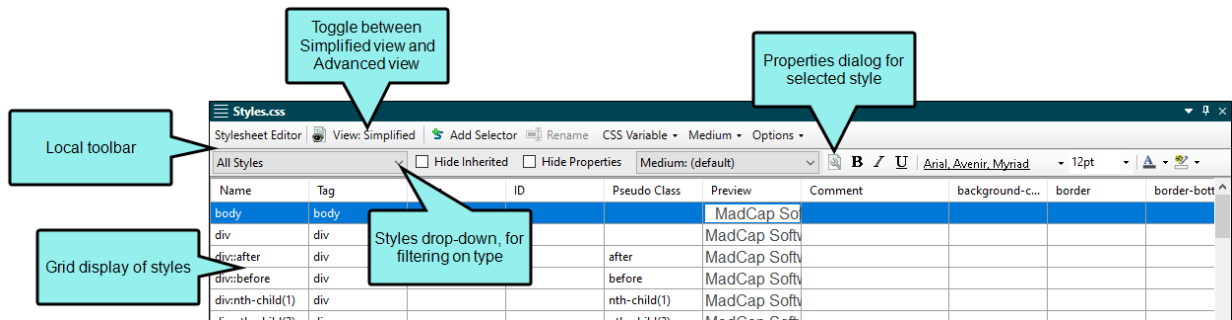

- How to Use the Simplified View 12
- How to Use the Advanced View16

I How to Use the Simplified View

1. Open the `Styles.css` file.
2. In the local toolbar of the Stylesheet Editor, make sure the first button is labeled **View: Simplified**.

If it says **View: Advanced**, click it so it changes to the Simplified view. The Simplified view displays styles in a grid. Take a moment to scroll through the styles in the stylesheet.

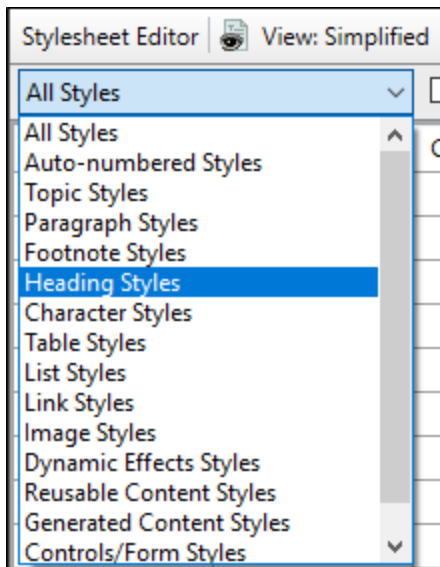

3. From the Content Explorer, double-click `Introduction.htm`. The topic opens in the XML Editor to the right. Notice the text has different styles applied.

- Click the **Styles.css** tab.

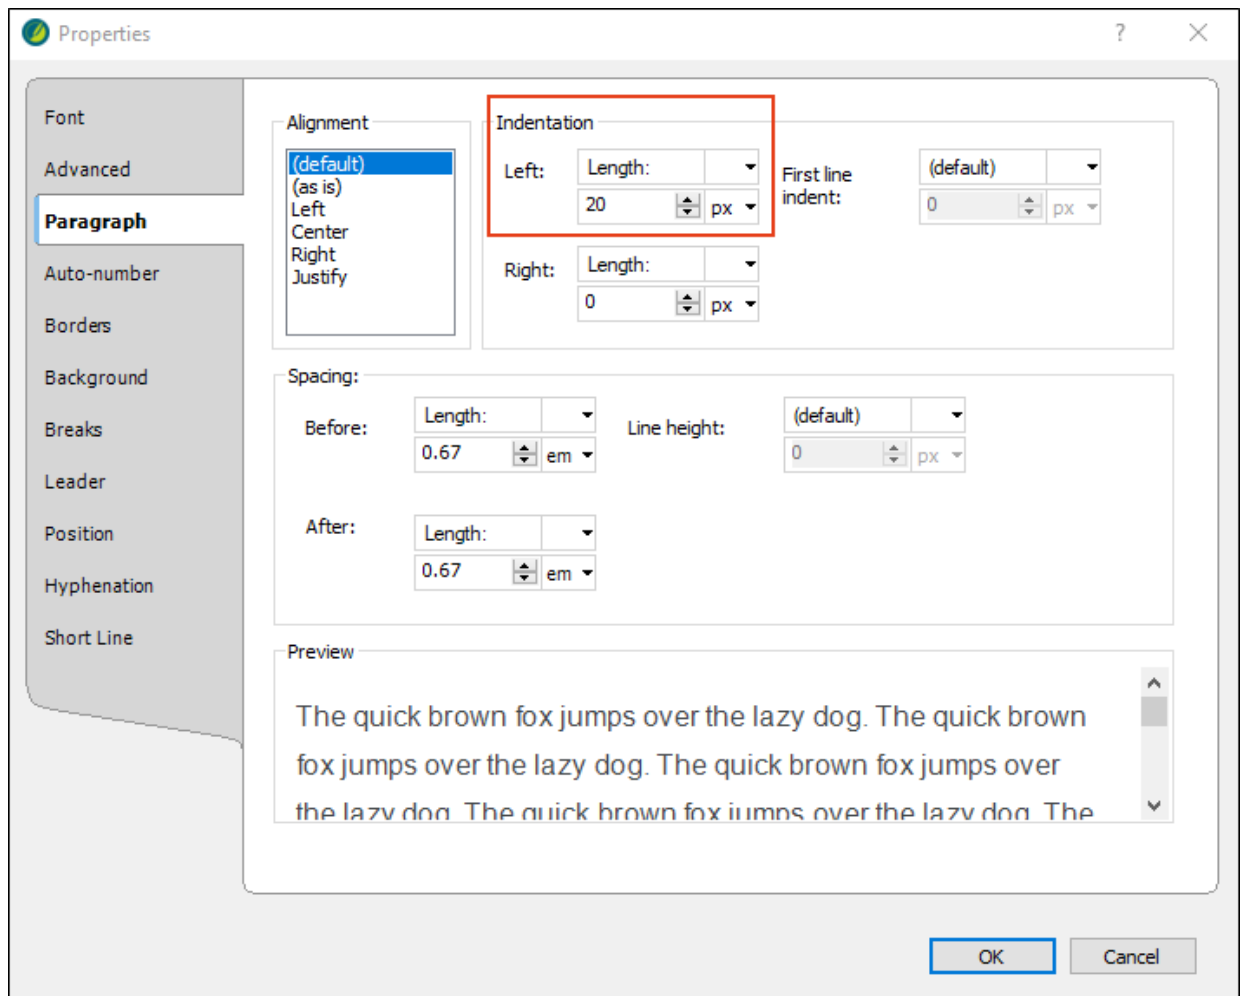

- From the **Styles** drop-down, select **Heading Styles**.

- In the grid, select the **h1** style element row.
- From the local toolbar **Font Family** drop-down, select **Georgia**.

8. From the local toolbar, click .
9. In the Properties dialog, select the **Paragraph** tab. In the **Indentation** section, type 20 for the left length. Click **OK**.

10. Click  to save your work.
11. Click off the **h1** row. The **Preview** column updates to show the new property value.

12. In the h1 row **Comment** column, double-click in the cell. At the cursor prompt, type `Use for first heading style`. Press **ENTER**.

Name	Tag	Class	ID	Pseudo Class	Preview	Comment	color	display	font-family	font-size
h1	h1				Mad	Use for first heading style	var(--Primary)	block	Georgia	24.0pt

NOTE Making comments in the stylesheet is a simple way to keep track of information related to the style. Comments can be viewed and edited in all the various places where one might interact with styles.

13. Click  to save your work.
14. Open **Introduction.htm**. Notice the new design for the heading style. In fact, open any of the topics in the Austin project, and notice all the h1 elements were affected by the modification in the stylesheet.

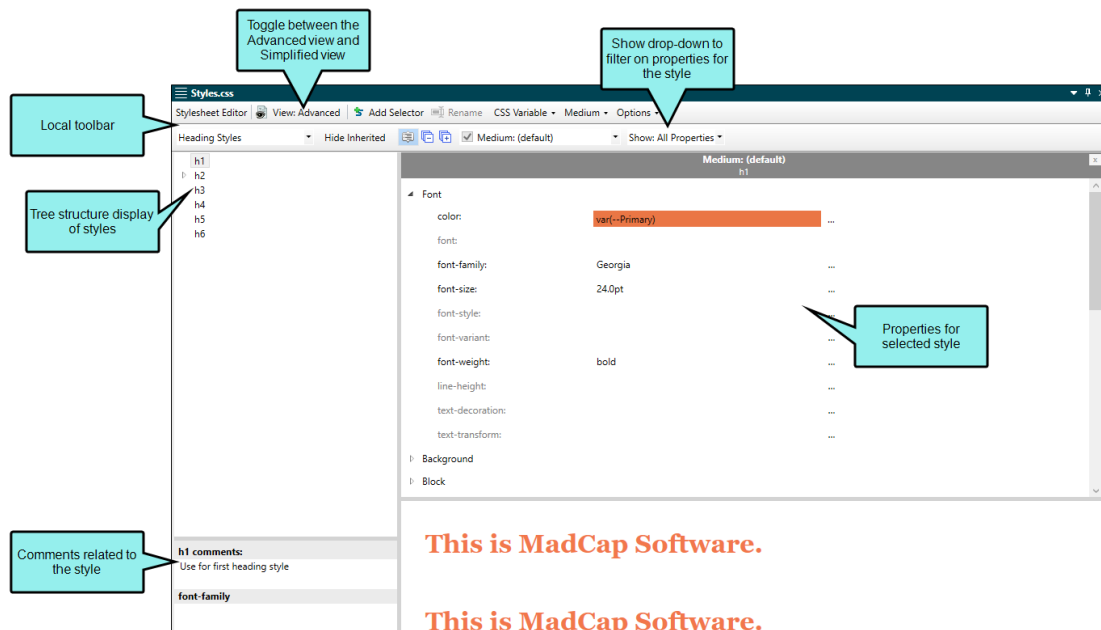

NOTE An advantage of using the Simplified view is that you can apply a property to multiple styles at a time.

I How to Use the Advanced View

1. In the Stylesheet Editor, toggle to **View: Advanced**.

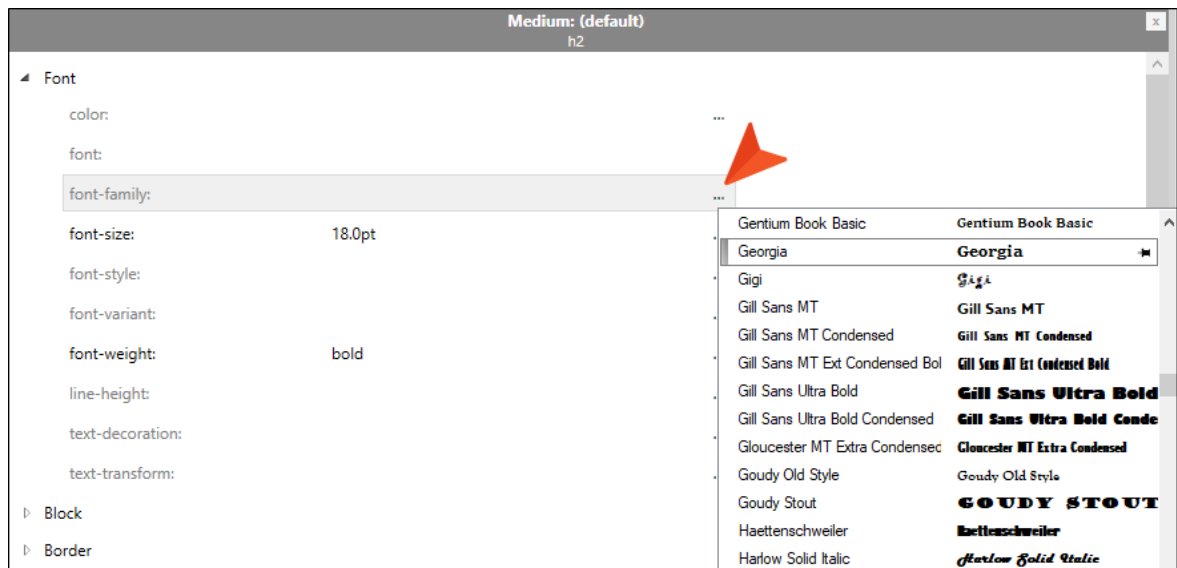

The Advanced view displays styles in a tree structure. More styles settings are available in the Advanced view compared to the Simplified view. The Advanced view retains the filtered heading styles with the font change, and the style comment. Let's do the same type of change, to get a feel for the different views.

2. In the left pane tree structure, select the **h2** style element.
3. In the right pane, the style properties display. Let's filter the properties that display for the h2 element. From the local toolbar, **Show** drop-down, select **Show: Assorted Relevant Properties**.

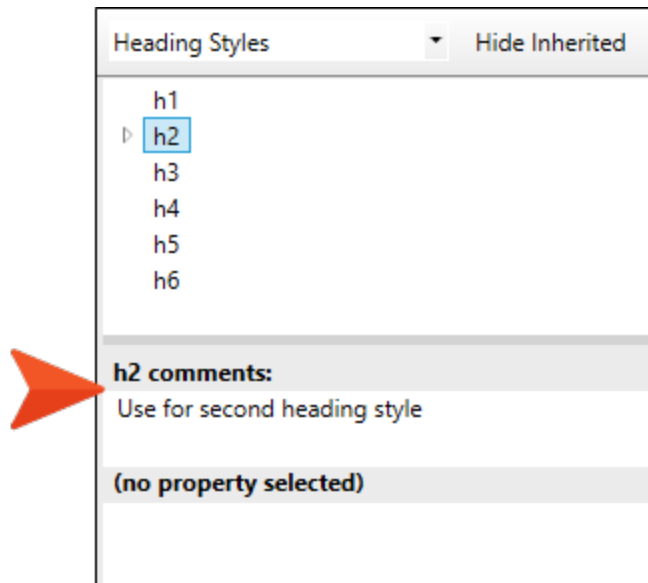

4. Style properties can be listed in alphabetical order or grouped together in categories. Let's ensure the properties are grouped, so we can find what we want faster. In the local toolbar, click  (Alphabetical view) to switch to  (Grouped view). (Your view might already be set to the Grouped view.)
5. Let's assign the same font as before. Expand the **Font** group.
6. Locate the **font-family** property, and click  to the right to select a value.
7. From the context menu, select **Georgia**.

 **NOTE** You might notice the font-family label is initially gray instead of a darker text. The gray text indicates there is an inherited style. An inherited style means it has no specific settings yet, and the style is inheriting default values from somewhere else. When you selected Georgia, the label changed from gray to the darker text. That means it is no longer inheriting its style. You have explicitly set a new value for the style.

8. In the **h2 comments** field, type `Use for second heading style`. This relates information about the style to other authors.

9. Click  to save your work.
10. Open **Introduction.htm**. The heading style has changed (as can be seen in all the topics containing the h2 element).

 **NOTE** An advantage of using the Advanced view is that you can see and apply settings to multiple mediums and media queries at the same time.

Style Tags in Flare Desktop Editors

In addition to the Stylesheet Editor, the XML Editor and Internal Text Editor are Flare Desktop’s primary editors when working with style elements. Once style properties are defined in the stylesheet, they can be applied to the content.

This chapter discusses the following:

- How to Identify Styles in the XML Editor 20
- How to Identify Styles in the Text Editor 26
- How to Edit a CSS File in the Text Editor 27

I How to Identify Styles in the XML Editor

Flare Desktop's structure bars are a great visual tool for identifying topic tags and page architecture. The bars provide information about content and the styles that are applied to that content.

Tag Bars

1. Open **Introduction.htm**. Let's look at styles from within the content file. The structure bars to the left of the content are "tag bars" that show blocks of content.

2. With the cursor in the XML Editor, hover your cursor over the **h1** structure bar. Notice it shows an `<h1>` tag which corresponds to the h1 heading to the right.

NOTE To show or hide tag bars, click  at the bottom of the XML Editor.

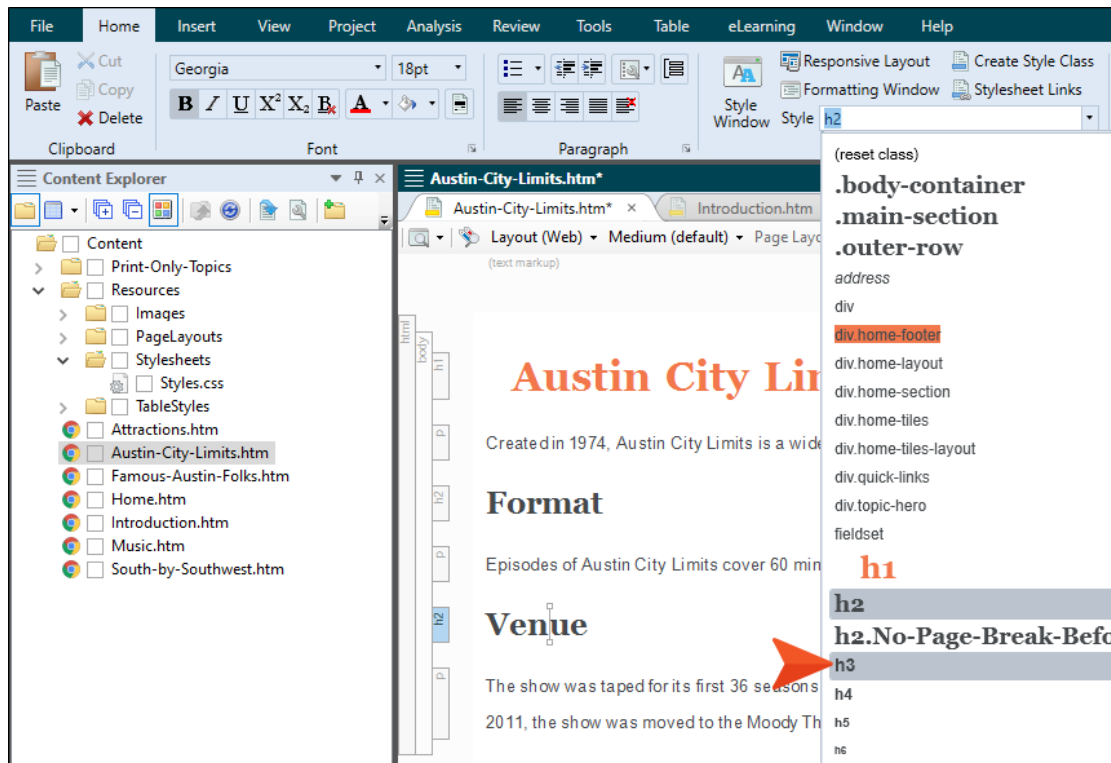

3. Let's edit the h1 heading. It might look better without the 20px indentation. We can take action from the structure bars directly. Right-click the **h1** tag bar.

4. From the context menu, select **Style Class > Edit Style Class**. The Styles.css file opens in the Advanced view.
5. In the left pane tree structure, ensure the **h1** style has focus (if not, select it).
6. From the local toolbar **Show** drop-down, select **Show: Set (Locally) Properties – properties set in this stylesheet**.
7. Expand the **Box** group. In the **margin-left** field, change the value to **0px**, and press **ENTER**.

8. Click  to save your work.
9. Go back to the **Introduction.htm** topic, and view the heading update.
10. Open **Austin-City-Limits.htm**. Let's apply a different style to the last heading.
11. Place your cursor anywhere in the "Venue" heading.

12. From the **Home** ribbon, select the **Style** drop-down, and choose **h3**. This is a quick way to apply a style to content.

 **NOTE** Notice the styles available in the Style drop-down are valid for block-level (e.g., h3, p, div) content only. If we were looking to apply a style to character-level (e.g., span, b) content, we would have to select the appropriate text within the block (e.g., heading, paragraph) first, and the styles in the drop-down would correspond to its type.

13. Click  to save your work.

Span Bars

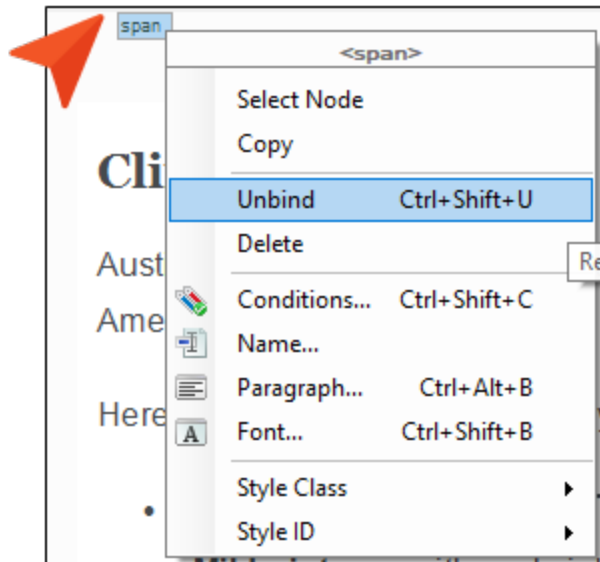

1. Open `Introduction.htm`.
2. Under the "Climate" heading, place your cursor within the bold phrase "long and hot summers." Notice the tag at the top part of the topic. This is a "span bar." These bars show formatting tags at the character level.

 **NOTE** To show or hide span bars, click  at the bottom of the XML Editor.

3. Hover your cursor over the span bar at the top. The phrase's style is ` class: Emphasis`.

4. Right-click the span tag, and select **Unbind**. The style is removed from the text.

5. Re-select the text “long and hot summers.”
6. From the **Home** ribbon, select **Style Window**. The Styles window pane opens to show you styles that are valid for character-level content.

 **NOTE** In the previous steps we selected styles from the Home > Style drop-down. You can also apply styles from the Floating Style Picker by pressing CTRL+SHIFT+H. As you can see, there are multiple ways to apply a style.

7. From the **Available Styles** section, select **span.Emphasis**. The content changes back to its original state.

8. Click  to save your work.

I How to Identify Styles in the Text Editor

An alternative way to view topic content or tags is through the Internal Text Editor. The editor displays the same information—just presented in a different way. Users who know their way around XHTML and CSS code might use the Text Editor more frequently.

1. Open `Introduction.htm`.
2. At the bottom of the topic, select the **Text Editor** tab.

3. From the local toolbar, click . By toggling the syntax colors off and on, it is easier to pinpoint how HTML and XHTML elements work hand in hand with CSS elements.

4. Notice how the `` class: `Emphasis` style is written in true code.

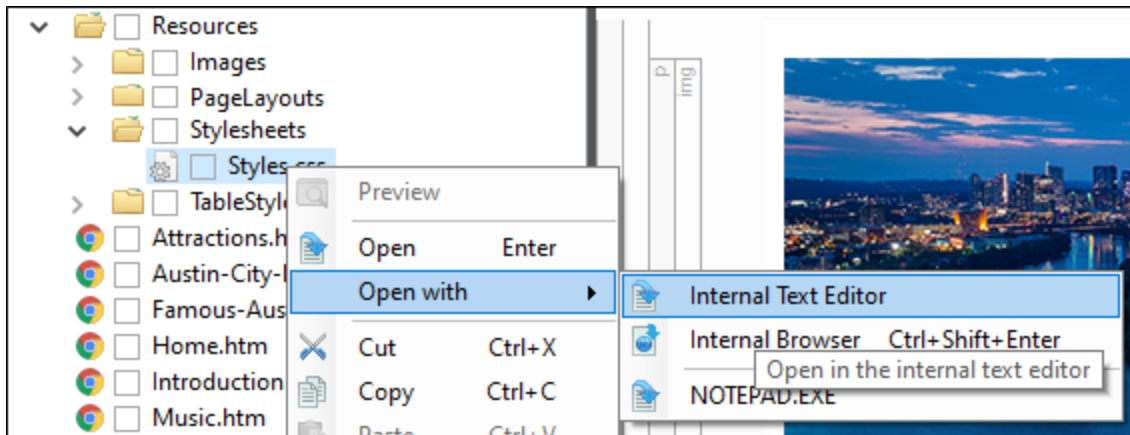

5. Select the **XML Editor** tab at the bottom to go back to the other view.

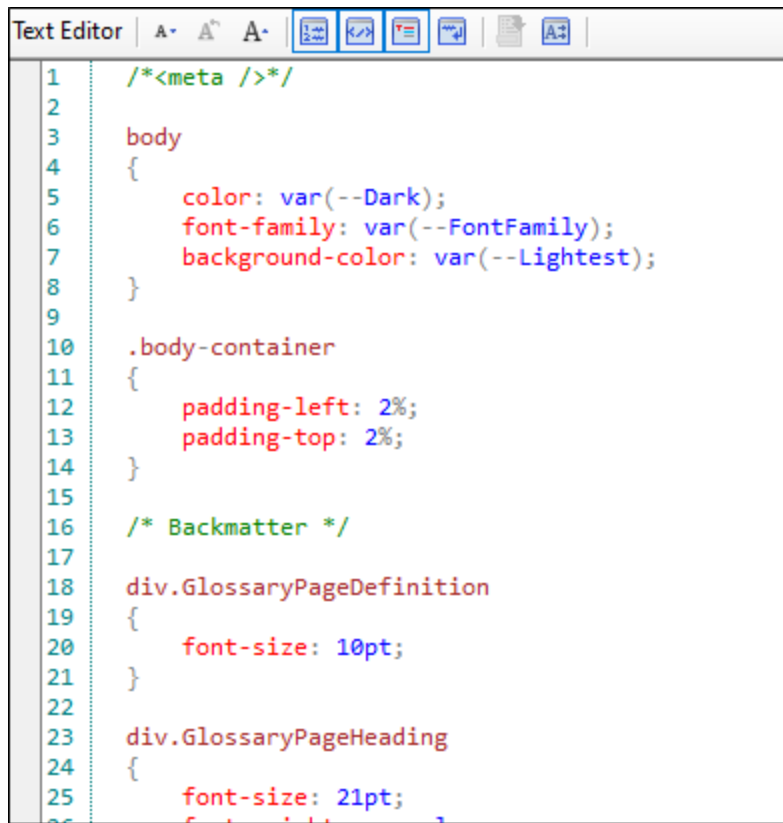

I How to Edit a CSS File in the Text Editor

The following steps introduce you to editing styles using the Text Editor. A full understanding of CSS code is in no way a requirement for using Flare Desktop, but it is helpful to know styles can be edited this way. More advanced users may find this editor useful.

1. From the Content Explorer, right-click the **Styles.css** file.
2. From the context menu, select **Open with**, and then select **Internal Text Editor**.

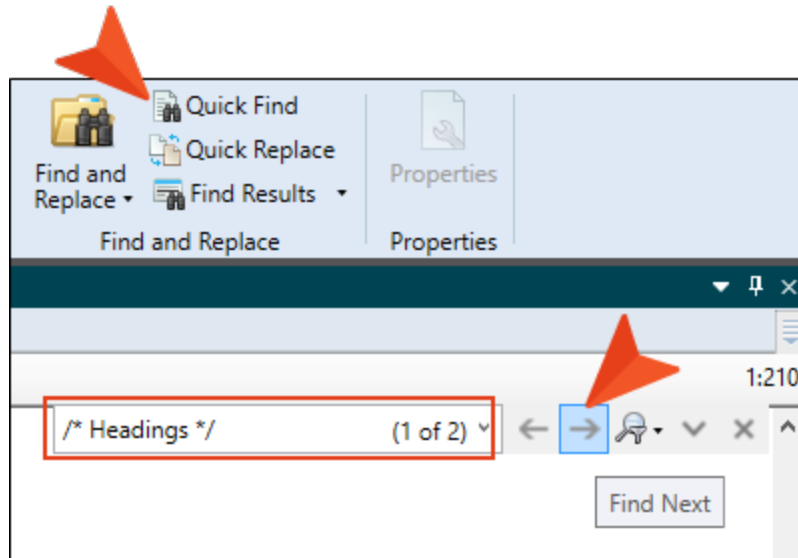

All the styles and properties from the Stylesheet Editor are displayed to the right in the Text Editor.

A screenshot of a 'Text Editor' window. The window has a title bar with the text 'Text Editor' and several icons. The editor area shows CSS code with line numbers on the left. The code includes a meta tag, a 'body' selector with color, font-family, and background-color properties using CSS variables, a '.body-container' selector with padding properties, a comment '/* Backmatter */', and two class selectors: 'div.GlossaryPageDefinition' with font-size: 10pt and 'div.GlossaryPageHeading' with font-size: 21pt. The code is color-coded: comments in green, selectors in red, and property values in blue.

```
1  /*<meta />*/
2
3  body
4  {
5      color: var(--Dark);
6      font-family: var(--FontFamily);
7      background-color: var(--Lightest);
8  }
9
10 .body-container
11 {
12     padding-left: 2%;
13     padding-top: 2%;
14 }
15
16 /* Backmatter */
17
18 div.GlossaryPageDefinition
19 {
20     font-size: 10pt;
21 }
22
23 div.GlossaryPageHeading
24 {
25     font-size: 21pt;
```

3. Scroll down to roughly line 210 to view the heading settings. Notice the property values reflect the updates we made in the Stylesheet Editor. (If you do not see line numbers to the left of the editor, from the local toolbar, click . This shows or hides the numbered lines.)

 **NOTE** You can conveniently search for items in the Text Editor. For the step above, from the **Home** ribbon, select **Quick Find**. You can type `/ * Headings */`. You might have to click through a few results until you find the one you want.

4. Let's change the font-family property for the h1 and h2 elements.
 - a. Under **h1**, locate the font-family property, and type `Arial`.
 - b. Under **h2**, locate the font-family property, and type `Arial`.

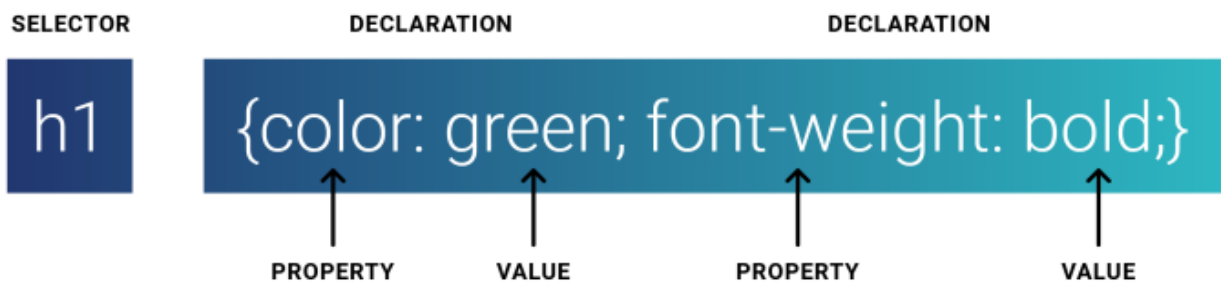

```
200  /* Headings */
201
202  h1 /*Use for first heading style*/
203  {
204      font-weight: bold;
205      font-size: 24.0pt;
206      color: var(--Primary);
207      font-family: Arial;
208      margin-left: 0px;
209  }
210
211  h2 /*Use for second heading style*/
212  {
213      font-weight: bold;
214      font-size: 18.0pt;
215      page-break-before: always;
216      font-family: Arial;
217  }
```

5. Click  to save all files.
6. Open the **Introduction.htm** topic (or any topic) to view the updated headings.
7. From the **Window** ribbon, select **Close All Documents**.

CHAPTER 6

Parts of a Style

A selector (e.g., `h1`, `p`) in a stylesheet includes a declaration made of two parts: properties and values. Examples of properties might be `color`, `font-weight`, or `font-size`. The values for those properties might be `red`, `bold`, and `14.0pt`.

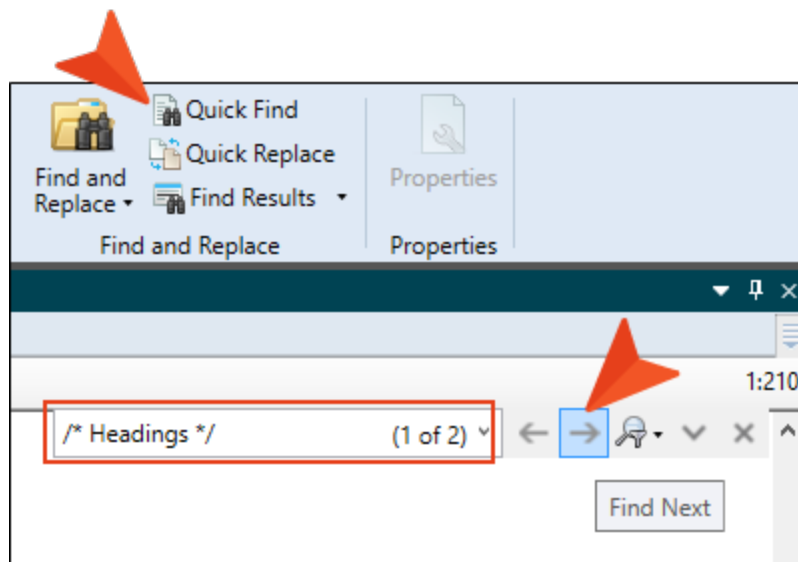

Getting to Know the Parts of a Style

Let's look at a style in true CSS code, and then how it looks in the stylesheet.

1. From the Content Explorer, expand **Resources > Stylesheets**, and right-click the **Styles.css** file.
2. From the context menu, select **Open with**, and then select **Internal Text Editor**. All the styles and properties from the Stylesheet Editor are displayed to the right in the Text Editor.
3. Scroll down to roughly line 234 to view the h3 heading settings.

```
233  
234 h3  
235 {  
236     font-weight: bold;  
237     font-size: 14.0pt;  
238 }  
239
```

 **NOTE** You can conveniently search for items in the Text Editor. For the step above, from the **Home** ribbon, select **Quick Find**. You can type `/* Headings */`. You might have to click through a few results until you find the one you want.

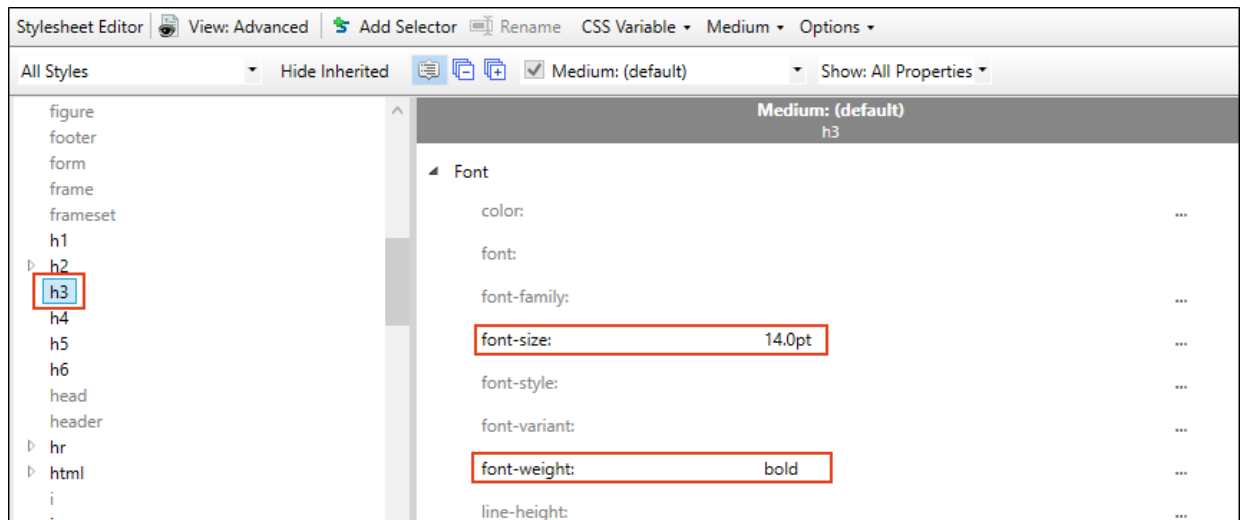

4. From the Content Explorer, double-click **Styles.css**.

- From the Stylesheet Editor's local toolbar, make sure the first button is labeled **View: Advanced**.

- Filter to see heading styles, and select the **h3** style element.
- From the local toolbar **Show** drop-down, select **Show: All Properties**.
- Expand the **Font** group. Notice how the style elements correlate between the Text Editor and the Stylesheet Editor. The h3 style (or selector) is paired with its own properties and values.

- From the **Window** ribbon, select **Close All Documents**.

Factory and Project Stylesheets

The following explains the difference between factory and project stylesheets.

- **Factory** When installing Flare Desktop, all of its program files, including factory stylesheets, are located in the Windows folder where you installed the product. These stylesheets contain style settings that might be used in your project, even though those stylesheets are not located in the project.
- **Project** You can add stylesheets to a project, but most project templates typically come with a stylesheet. For example, the Austin template project comes with a stylesheet file (Styles.css). This is a project stylesheet because it is located within the project. In many cases, your content might use style values from a factory stylesheet automatically. If you provide specific settings in a project stylesheet, and they conflict with settings from a factory stylesheet, the values from the project stylesheet have precedence.

This chapter discusses the following:

How to View Inherited Property Values	35
How to Set a Value in the Project Stylesheet	36

I How to View Inherited Property Values

The steps below show how a style property value is inherited from a factory stylesheet.

1. From the Content Explorer, expand **Resources > Stylesheets**, and double-click the **Styles.css** file.
2. From the **Styles** drop-down, select **All Styles** (if not already shown).
3. In the left pane tree structure, notice the styles listed. Some display as a light gray, and some are shown in a darker font. (If the tree structure displays only darker items, click **Hide Inherited** in the local toolbar.)

Style elements that display in gray indicate that the style is inheriting its default values from somewhere else (e.g., factory stylesheet). An inherited style means it has no specific settings yet in the project's stylesheet. When you explicitly set a new value for the style, the label changes from gray to the darker text (meaning it is no longer inheriting its style).

4. Hover your cursor over the **abbr** gray style element. A Windows path displays, showing where the inherited information is coming from. The stylesheet is located outside of the project.

NOTE The **abbr** tag defines an abbreviation or acronym. The acronym tag is not supported in HTML5, so we will edit the **abbr** element.

I How to Set a Value in the Project Stylesheet

The steps below change a property value in the project stylesheet, so it is no longer inherited from the factory stylesheet.

1. Select **abbr**.
2. From the local toolbar, **Show** drop-down, select **Show: Set (Locally) Properties - properties set in this stylesheet**.
3. In the **Add Properties** drop-down, select **color**.

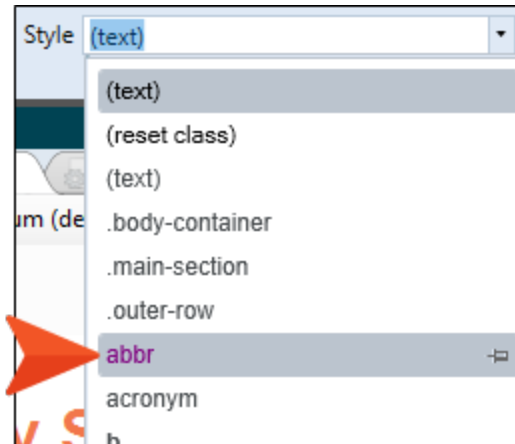

4. In the **Color Property** field, replace the default property "inherit," by typing a new value of **Purple**, and press **ENTER**. Notice the **abbr** item has changed to the darker font.

NOTE The value of a color can be set by typing the name of the color, a color hex code, or selecting a color from the color palette. Additionally, you can interact with the Color Picker dialog to set a color, or engage the cursor to pick a screen color.

5. Click  to save your work.
6. Open the **South-by-Southwest.htm** topic.
7. Select the "SXSW" text.

- From the **Home** ribbon, **Style** drop-down, select the **abbr** style element.

- Click off the selected text to see that it turned purple in the XML Editor.

 **NOTE** If you do not see the style preview (purple) in the **Style** drop-down, the option to do so is probably not set. To set it, go to **File > Options**. In the Options dialog, select the **XML Editor** tab, and then select **Show style previews in UI**.

- Click  to save your work.

Using Stylesheets vs. Local Formatting

Local formatting can be very attractive because it is quick and easy. However, it is recommended that you use styles instead of local formatting whenever possible. Although local formatting is very convenient in the short-term, using styles is much more efficient and can save you a great deal of time in the long-term.

This chapter discusses the following:

- How to Apply Local Formatting39
- How to Remove Local Formatting40
- How to Use a Stylesheet for Applying Styles41

I How to Apply Local Formatting

1. From the Content Explorer, open **Music.htm**. We decide the paragraph text looks too small, and we want to make it bigger in all topics. Let's start changing it.
2. Select (left-click) the **p** structure bar so that the entire paragraph is highlighted.
3. From the **Home** ribbon, click the **Font Size** drop-down, and choose **14pt**.

4. Click  to save your work.
5. Open **South-by-Southwest.htm**.
6. Select the two paragraphs. (You can click and drag to select the text. Or you can press and hold **SHIFT**, and then click the **p** structure bars to select the text.)
7. From the **Home** ribbon, click the **Font Size** drop-down, and choose **14pt**.
8. Click  to save your work.

I How to Remove Local Formatting

Since we added local formatting to a couple files in our project, let's remove that formatting before using a stylesheet.

1. Open **Music.htm**.
2. Press **CTRL+A** to select all of the topic's content.
3. From the **Home** ribbon, **Font** section, click .
4. Click  to save your work.
5. Open **South-by-Southwest.htm**. Repeat the above steps to remove the local formatting.

 **NOTE** Removing local formatting is important because of style precedence. Flare Desktop lets you have multiple stylesheets (primary and local) set on different files and at different levels. Therefore, you need to understand how precedence works, both in the interface (editors) and the output. In general, the closer something is to the source, the higher its precedence will be. For example, local formatting is close, whereas a factory stylesheet installed with Flare Desktop is farther away.

I How to Use a Stylesheet for Applying Styles

Changing the style by local formatting was quick for the first two topics. But this could get time-consuming if we continue to change the font size for every paragraph in all the topics. Is there a more efficient way? Yes, and that way is through using a stylesheet.

1. Open the **Styles.css** file. Let's work in the Advanced view.
2. From the **Styles** drop-down, select **Paragraph Styles**, and select the **p** style.

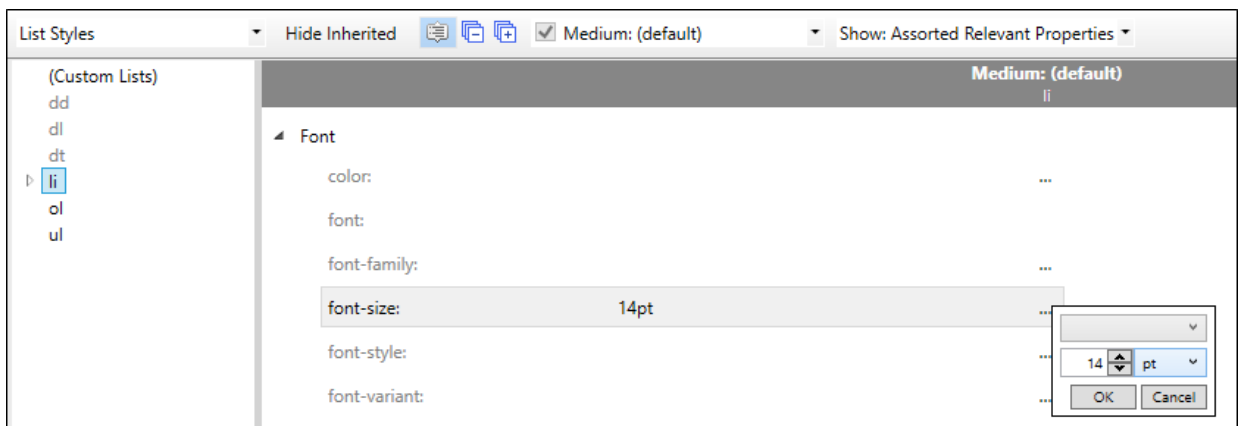

3. Expand the **Font** group.
4. Find **font-size**, and click .
5. From the pop-up window, change the font size to **14pt**, and select **OK**.
6. Click  to save your work.

7. Since there are some list items in the project, let's change the font size on the list styles so all the text appears as the same size. From the **Styles** drop-down, select **List Styles**, and then select **li**.

8. From the local toolbar, **Show** drop-down, select **Show: Assorted Relevant Properties**. (Your view might already show this filter.)
9. Expand the **Font** group, and next to **font-size**, click .
10. From the pop-up window, change the font size to **14pt**, and select **OK**.

11. Click  to save your work.
12. Open any topic file and see the text has been styled to the larger size—all at once! Using a stylesheet will make the maintenance, and any future updates, easier to manage.
13. From the **Window** ribbon, select **Close All Documents**.

EXAMPLE You are working on a project that has 100 topics. Your corporate style guide says to use a red, italic font style for text referring to an interface item. As you are writing content, it seems natural and easy to use local formatting from the Home ribbon to style the necessary text (which appears in half your topics). A few weeks after you finish the project, the corporate style guide is updated to write interface items in a bold font style. You have to go back through all your content to find the 50 topics referring to the interface, and manually make edits.

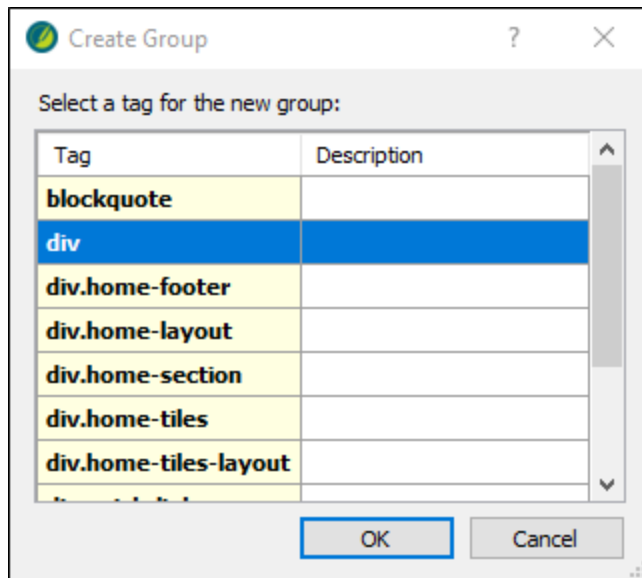

CHAPTER 9

Nested Tags

When one HTML tag is contained within another, it is nested and therefore can inherit the style settings from the outer tag.

I How to Edit Nested Style Elements

1. From the Content Explorer, open **Austin-City-Limits.htm**.
2. At the end of the "Format" section, create an empty paragraph.
3. From the **Home** ribbon, click . This groups selected items.
4. From the Create Group dialog, select **div**. Click **OK**.

5. Type **Willie Nelson was the first featured performer**. Notice the default paragraph font color is black.

6. Open **Styles.css**.
7. From the **Styles** drop-down, select **All Styles**.
8. In the left pane tree structure, select the **div** style.
9. From the local toolbar, **Show** drop-down, select **Show: Set (Locally) Properties - properties set in this stylesheet**.

10. In the **Add Property** drop-down, select **color**.

11. In the **Color Property** field, replace the default property "inherit," by typing a new value of **Purple**. Press **ENTER**.

 **NOTE** You might not see the purple color display right away, and that is okay. When you press **ENTER** and save the stylesheet, those actions enforce the style update.

12. Click  to save all files.
13. Open the **Austin City Limits** topic. Since the **p** element is within the **div** element (and the **div** is the wrapping container tag that holds the style), the paragraph text within the **div** inherits the **div** style of purple font.

14. In the stylesheet, select the **p** style.
15. In the **Add Property** drop-down, select **color**.

16. In the **Color Property** field, replace the default property "inherit," by typing a new value of Gray. Press **ENTER**.

17. Click  to save your work.
18. Open the topic again. Since the p element is within the div element, it is "closer" to the source, and the text turns gray.

19. Open **Famous-Austin-Folks.htm**. Let's change the color on the list styles so all the text in the project appears the same.
20. Open **Styles.css**.
21. From the **Styles** drop-down, select **List Styles**, and then select **li**.
22. In the **Add Property** drop-down, select **color**.
23. In the **Color Property** field, replace the default property "inherit," by typing a new value of Gray. Press **ENTER**.
24. Click  to save all files.
25. Go back to the **Famous Austin Folks** topic to check the list items color update.
26. From the **Window** ribbon, select **Close All Documents**.

 **NOTE** Cascading stylesheet (CSS) rules account for cascading order, specificity, and inheritance. All of which determine the look and feel of the project.
